2. Over time, the average membership size of HMO's has risen, often as a result of mergers and acquisitions. Can this be explained by economies of scale in managing HMO's? (Wholey et. al. & Given, 1996)

HEALTH ECONOMICS
PRACTICE PROBLEM
SANTERRE & NEUN, CHAPTER 7

Santerre & Bennett (1992) estimated the short-run total variable cost function for a sample of 55 for-profit hospitals in Texas (t-statistics are in parentheses below the estimated coefficients).

\[
\ln \text{STVC} = 1.31 + 0.47 \ln q + 0.80 \ln w + 0.73 \ln \text{QUALITY} + 0.11 \ln \text{CASEMIX} + \\
(0.69) \quad (3.31) \quad (4.42) \quad (2.58) \quad (1.48) \\
0.29 \ln k + 0.07 \ln \text{DOC} + \text{Other factors} \\
(3.16) \quad (0.88)
\]

Adjusted \( R^2 = 0.95 \) \quad N=55

where STVC = short-run total variable cost, \( q \) = a measure of output (total inpatient days), \( w \) = average wage rate or price of labor, QUALITY = a measure of quality (number of accreditations), CASEMIX = an indicator of patient case-mix (number of services), \( k \) = a measure of capital (beds), and DOC = number of admitting physicians. All variables are expressed as natural logarithms (ln), so the estimated coefficients can be interpreted as elasticities.

How much of the variation in STVC is explained by the explanatory variables? How do you know that?

Which of the estimated coefficients are not statistically significant? Explain.

Does the estimated coefficient on output represent short-run economies or diseconomies of scale? Explain.

What are the expected signs of the coefficient estimates on \( w \), QUALITY, and CASEMIX? Explain.

Provide an economic interpretation of the magnitude of the estimated coefficient on \( w \).
Interpreting an Estimated Cost Function

Examples:

1. On the Estimation of Hospital Cost Functions (D.F. Vitaliano, 1987)

\[ Total\ Cost = -1,317,441 + 64,303\ Beds + 24.57\ Beds^2 \]
\[ (-2.49) \quad (10.22) \quad (2.30) \]

\[ + 5,194,528\ Med.\ schl. + 206,373\ Urban \]
\[ (3.85) \quad (1.73) \]

(t-statistics in parentheses)
